**Oral health**

**Key facts**
- Oral diseases are the most common noncommunicable diseases (NCDs) and affect people throughout their lifetime, causing pain, discomfort, disfigurement and even death.
- The Global Burden of Disease Study 2016 estimated that oral diseases affected half of the world’s population (3.58 billion people) with dental caries (tooth decay) in permanent teeth being the most prevalent condition assessed.
- Severe periodontal (gum) disease, which may result in tooth loss, was estimated to be the 11th most prevalent disease globally.
- Severe tooth loss and edentulism (no natural tooth) was one of the leading ten causes of Years Lived with Disability (YLD) in some high-income countries.
- In some Asian-Pacific countries, the incidence of oral cancer (cancer of the lip and oral cavity) is within the top 3 of all cancers.
- Dental treatment is costly, averaging 5% of total health expenditure and 20% of out-of-pocket health expenditure in most high-income countries.
- The oral health care demands are beyond the capacities of the health care systems in most low- and middle-income countries (LMICs).
- Oral health inequalities exist among and between different population groups around the world and through the entire life course. Social determinants have a strong impact on oral health.
- Behavioural risk factors for oral diseases are shared with other major NCDs, such as an unhealthy diet high in free sugars, tobacco use and harmful use of alcohol.
- Poor oral hygiene and inadequate exposure to fluoride have negative effects on oral health.

**Oral diseases and conditions**
Seven oral diseases and conditions account for most of the oral disease burden. They include dental caries (tooth decay), periodontal (gum) diseases, oral cancers, oral manifestations of HIV, oro-dental trauma, cleft lip and palate, and noma. Almost all diseases and conditions are either largely preventable or can be treated in their early stages.

The Global Burden of Disease Study 2016 estimated that oral diseases affected at least 3.58 billion people worldwide, with caries of the permanent teeth being the most prevalent of all conditions assessed.

Globally, it is estimated that 2.4 billion people suffer from caries of permanent teeth and 486 million children suffer from caries of primary teeth.

In most LMICs, with increasing urbanization and changes in living conditions, the prevalence of oral diseases continues to increase notably due to inadequate exposure to fluoride and poor access to primary oral health care services. Heavy marketing of sugars, tobacco and alcohol leads to growing consumption of unhealthy products.

For more information on oral health please visit: [https://www.who.int/news-room/fact-sheets/detail/oral-health](https://www.who.int/news-room/fact-sheets/detail/oral-health)
A syndromic surveillance system is good for early detection of and response to public health events.

Sentinel surveillance occurs when selected health facilities (sentinel sites) form a network that reports on certain health conditions on a regular basis, for example, weekly. Reporting is mandatory whether or not there are cases to report.

Jamaica’s sentinel surveillance system concentrates on visits to sentinel sites for health events and syndromes of national importance which are reported weekly (see pages 2 - 4). There are seventy-eight (78) reporting sentinel sites (hospitals and health centres) across Jamaica.

### Map representing the Timeliness of Weekly Sentinel Surveillance Parish Reports for the Four Most Recent Epidemiological Weeks - 4 to 7 of 2020

Parish health departments submit reports weekly by 3 p.m. on Tuesdays. Reports submitted after 3 p.m. are considered late.

### REPORTS FOR SYNDROMIC SURVEILLANCE

#### FEVER
Temperature of >38°C /100.4°F (or recent history of fever) with or without an obvious diagnosis or focus of infection.

#### KEY
VARIATIONS OF BLUE SHOW CURRENT WEEK

#### WEEKLY VISITS TO SENTINEL SITES FOR UNDIFFERENTIATED FEVER ALL AGES 2020 vs WEEKLY THRESHOLD; JAMAICA
**FEVER AND NEUROLOGICAL**
Temperature of >38°C /100.4°F (or recent history of fever) in a previously healthy person with or without headache and vomiting. The person must also have meningeal irritation, convulsions, altered consciousness, altered sensory manifestations or paralysis (except AFP).

**FEVER AND HAEMORRHAGIC**
Temperature of >38°C /100.4°F (or recent history of fever) in a previously healthy person presenting with at least one haemorrhagic (bleeding) manifestation with or without jaundice.

**FEVER AND JAUNDICE**
Temperature of >38°C /100.4°F (or recent history of fever) in a previously healthy person presenting with jaundice.

The epidemic threshold is used to confirm the emergence of an epidemic in order to implement control measures. It is calculated using the mean reported cases per week plus 2 standard deviations.
ACCIDENTS
Any injury for which the cause is unintentional, e.g. motor vehicle, falls, burns, etc.

KEY
VARIATIONS OF BLUE SHOW CURRENT WEEK

VIOLENCE
Any injury for which the cause is intentional, e.g. gunshot wounds, stab wounds, etc.

GASTROENTERITIS
Inflammation of the stomach and intestines, typically resulting from bacterial toxins or viral infection and causing vomiting and diarrhoea.

**Weekly visits to Sentinel Sites for Influenza-like Illness (ILI)**

**All ages 2020 vs Weekly Threshold; Jamaica**

**Jamaica: Percentage of Hospital Admissions for Severe Acute Respiratory Illness (SARI 2020) (compared with 2011-2019)**

**Epi Week Summary**

During EW 07, 12 (twelve) SARI admissions were reported.

13.6% positivity for EW 07

**Caribbean Update EW 07**

Overall, influenza activity is moderate in the sub-region. Influenza activity slightly increased in Belize with influenza A(H1N1)pdm09 and influenza B viruses co-circulating. In the French Territories influenza-like illness is above the epidemic threshold with influenza A(H1N1)pdm09, and B/Victoria viruses co-circulating. In Jamaica, influenza activity continued increased with influenza B/Victoria predominance and influenza A(H1N1)pdm09 co-circulating.

** figure as at February 20, 2020

Only PCR positive dengue cases are reported as confirmed.

IgM positive cases are classified as presumed dengue.

Suspected dengue cases for 2018 and 2019 versus monthly mean, alert, and epidemic thresholds

Points to note:

- ** figure as at February 20, 2020
- Only PCR positive dengue cases are reported as confirmed.
- IgM positive cases are classified as presumed dengue.
ABSTRACT

Validating Tobacco and Marijuana Smoking in Jamaican Adults with Sickle Cell Disease Using Biochemical Tests

Antoinette Barton-Gooden1, Monika Asnani2 Devon Noonan3

Aim: Assess smoking prevalence and validate self-reported tobacco and marijuana smoking using biochemical measurements in adults with sickle cell disease.

Methods: A cross-sectional study was conducted at the sickle cell clinics during May-July 2019. Data collection tools included: socio-demographic instrument and a modified WHO Stepwise Approach to chronic disease risk factor surveillance (STEPS). Self-reported smoking and exposure were validated by carbon monoxide (CO) Breathalyzer (cutoff 6ppm), urine cotinine measures (cutoff 200ng/ml) and Tetrahydrocannabinoid (THC) tests (cutoff 50ng/ml). Data were analyzed using SPSS version 20.

Results: The sample of 220 adults consisted of 129 (58.6%) females. The majority had urban residence (51.4%); were employed (66.4%) and the mean age (34 ±11.76). Smoking prevalence was 15%. Self-reported tobacco ‘vs’ marijuana smoking was (10.9% ‘vs’ 10.5%) and concomitant tobacco and marijuana smoking (9.1%; χ² 65.965 p<0.001). Men had higher smoking (72.7% ‘vs’ 27.3%, Fisher’s Exact <0.001). There were higher occasional tobacco and occasional marijuana smoker (7.3% vs 6.8%) than daily smokers (3.6%). Only one smoker reportedly vaped tobacco. Regression analysis for current smoker revealed that only male gender was significant (OR 3.78, p=0.002). Comparison between self-reported smoking and urine tests revealed that the majority of tobacco smokers had positive cotinine results (88.9%; p<0.001); while (66.7%; p<0.001) of marijuana smokers had positive THC results. One positive THC tester disclosed using marijuana sublingual medication for pain. Mean carbon monoxide: Smokers ‘vs’ non-smokers were [13.63±7.88 ‘vs’ 8.9±3.45; p=0.002].

Conclusion: Males with SCD had high smoking prevalence. Cotinine and THC tests are reliable tests to assess smoking in SCD, but CO test is not.
